ABSTRACT

Systems and methods for transferring imaging information using network-based imaging techniques are disclosed. A system may comprise a server and a computing device coupled to each other via a network. In some embodiments, a select image(s) is associated with a default composition. The default composition comprises the necessary information for a device to acquire and construct the underlying image(s). A method for transferring imaging information, can be summarized by the following steps: accessing a remote-data server, selecting image information resident on the remote-data server to generate a composition, accessing an imaging-destination service, and communicating the composition to the imaging-destination service.
